A framework to map pore volume change and mineral dissolution/precipitation of wellbore cement exposed to high concentration CO₂ using micro-CT images

Monday, 31 May 2021 15:25 (15 minutes)

In this study, an image processing framework was proposed for mapping Ca(OH)₂ dissolution, CaCO₃ precipitation, and pore volume change of wellbore cement samples exposed to high concentration CO₂ under laboratory-simulated geologic CO₂ storage conditions. The main workflow covered in this framework is to, 1) remove noises, artifacts, beam hardening effects, etc. from micro-CT images of cement samples before and after reaction with CO₂; 2) register cement CT images before and after reaction; 3) generate grayscale intensity difference images showing CO₂-induced cement alteration, and convert grayscale intensity difference into X-ray attenuation coefficient change; 4) calculate pore volume change and local content changes of Ca(OH)₂ and CaCO₃ at each voxel, given X-ray attenuation coefficient change; 5) generate pore volume change and Ca(OH)₂/CaCO₃ content changes in 3D view. The effectiveness of the framework was validated through a step-by-step demonstration of results when deploying the framework to process the micro-CT images of six cement samples acquired before and after reaction with CO₂. The 3D CaCO₃ precipitation and Ca(OH)₂ dissolution map was obtained, and the internal and external CaCO₃ shells were visualized. Overall, the 3D precipitation and dissolution map gives more intuitive and interpretable results of CO₂-induced alteration of cement than the direct visual comparison from original CT images.
