Water Impact on Adsorbed Oil Detachment from Mineral Surfaces by Supercritical CO₂

Monday, 13 May 2024 14:55 (1h 30m)

Geochemical reactions are crucial for in-situ CO₂ mineralization underground associated with CO₂-enhanced oil recovery (CO₂-EOR) in a hydrocarbon reservoir. However, the presence of formation water and adsorbed oil on rocks generates physical barriers to CO₂'s access to mineral surfaces, which may yield impedance to CO₂ mineral trapping that has yet to be accounted for. In this study, we mimic the dynamic oil detachment process using molecular dynamic (MD) simulations and analyzed the influence of an adsorbed oil film on supercritical CO₂ (scCO₂) diffusion towards the mineral surface in the presence and absence of a water phase. CO₂-oil-water-rock reaction experiments are performed to substantiate the simulated data. Our results demonstrate a negative impact of water on oil film detachment by scCO₂, which may give rise to a substantial delay in mineral reactions or even impede their occurrence and is unfavorable for mineralized CO₂ storage underground. Carbonated water, regardless of whether it is saturated, showcases the same inhibitory effect on the miscibility of scCO₂ and oil, thereby restraining oil film detachment and the contact of CO₂ with the rock surface.
